Bruges, Belgium. 14-18 September 2011

Background
There is a paucity of evidence-based data for the treatment of primary systemic vasculitis (PSV) in childhood, partly due to the lack of a standardised outcome-measure for use in clinical trials. The Paediatric Vasculitis Activity Score (PVAS) is a quantitative clinical-index of manifestations of active disease, divided into 9 organ sub-systems.

Objective
To provide preliminary validation of the PVAS.

Methods
Children at Great Ormond Street Hospital NHS Trust with a diagnosis of PSV underwent simultaneous assessment of disease activity by 2 assessors. Scores were assessed for inter-observer variability and correlation with the physician’s global assessment of disease activity (PGA), ESR and CRP. Patients with newly diagnosed PSV were assessed twice: at diagnosis and 1 month, to assess tool-responsiveness to a change in disease state.

Results
23 children with PSV were studied - 48% male, 52% female. The diagnoses were: Behçet’s disease (n=7), Wegener’s granulomatosis (n=5), polyarteritis nodosa (n=5), cutaneous leukocytoclastic vasculitis (n=3), Cogan’s syndrome (n=1), microscopic polyangiitis (n=1) and unclassified vasculitis (n=1). Median PVAS was 1.5 (range 0-38). Bland-Altman analysis demonstrated high inter-observer agreement and Kappa analysis showed perfect agreement for 8/9 organ-system scores (K=1, p=0.00). Spearman’s rank showed correlation between PVAS and PGA ($r_s=0.87$, 95%CI=0.71 to 0.94, p=0.00) and CRP ($r_s=0.54$, 95%CI=0.10 to 0.81, p=0.02) but no correlation with ESR ($r_s=-0.1$). Four newly diagnosed patients demonstrated a fall in the PVAS in response to therapy (change in median from 13.5/63 to 3.5/63), with good agreement for this change between assessors.

Conclusion
This study provides preliminary evidence that PVAS is a useful clinical measure of vasculitis disease-activity with good inter-observer reliability and correlates highly with the PGA and CRP.
